1 Introduction

cl-config is a configuration library for Common Lisp

You can get a copy and this manual at http://common-lisp.net/project/cl-config

1.1 Summary

cl-config is a configuration library for Common Lisp

1.2 Installation

To install cl-config, start a Common Lisp session and type the following:

```
CL-USER> (require :asdf-install)
CL-USER> (asdf-install:asdf-install 'cl-config)
```

1.3 Feedback

Mail marianomontone at gmail dot com with feedback

1.4 Conventions

Hear are some coding conventions we'd like to follow:

- We do believe in documentation. Document your dynamic variables, functions, macros and classes. Besides, provide a documentation from a wider perspective. Provide diagrams and arquitecture documentation; examples and tutorials, too. Consider using an automatic documentation generator (see the bitacora package in the dependencies).
- We don't want functions to be shorter than the should nor longer than they should. There is no "every function should have at most ten lines of code" rule. We think that coding is like literature to a great extent. So you should strive for beauty and clarity. Again, that your code is object oriented doesn't imply that your methods will ideally have two lines of code and dispatch to somewhere else; that is not always good at all. It may be good from an object oriented point of view, but it is too low level. We want to think in terms of languages, that is higher level, instead of objects sending messages.
- Use destructuring-bind or let or a pattern-matching library instead of car, cdr, cadr, and the like to obtain more readable code.
- Use widely known Common Lisp coding guidelines: http://web.archive.org/web/20050305123711/www

2 Overview

CL-CONFIG is a configuration library for Common Lisp.

The idea is to define configuration-schemas and get a proper way of:

- Sharing and versioning your project's configuration schemas, but not your configurations. That way, you avoid overwriting configurations from different coders. Each coder has his own configurations that need to match the configuration schemas in the project. Whenever a project's configuration schema changes, each coder is reponsible of updating his configurations to match the new schemas.
- Being able to define configuration schemas declaratively.
- Provide configurations documentation and validation.
- Edit configurations from a GUI.
- Define your own option configurations types and provide validation for them.

3 Configuration schemas

Configuration schemas define the structure of a configuration.

The syntax to define configuration schemas is the following:

Where:

- configuration-schema-name is the name of the configuration-schema and the configuration-schema is globally identified by it. See find-configuration-schema
- parent-configuration-schema is the configuration schema we inherit from. Inheriting from a configuration schema means adding its sections to the child schema. Configuration schemas can inherit from several parents
- configuration-schema-title is a string describing very shortly the configuration schema. It is used to display configuration schemas from the editing GUI. It is a required argument.
- configuration-schema-documentation is the configuration schema documentation. This is not a required argument. It is also used from the editing GUI and is very useful for the configuration schema user.

Each configuration schema section follows this syntax:

```
(:section section-identifier section-title
  [(:documentation section-documentation)]
  {option-schema}*)
```

Where:

- section-identifier is a keyword that uniquely identifies the section
- section-title is a string describing very shortly the section. It is used to display sections from the editing GUI.

And option schemas are specified like this:

```
(option-identifier option-title option-type {option-parameter*}) where:
```

- option-identifier is a keyword that uniquely identifies the option
- option-title is a string describing very shortly the option. It is used to display sections from the editing GUI.
- option-type is the option type. There are different ways of specifying an option type, depending on the type.
- option-parameters may be:
 - :documentation followed by the documentation string. To document the option.
 - default followed by the default option value. If the configuration leaves the option unspecified, then it has the default value.

- optional, followed by true (t) of false (nil). Determines if the option value can be left unspecified. Default is false.
- avanced, followed by true (t) or false (nil). Determines if the option category is "advanced" (default is false)

Here is a simple example:

That is a typical configuration schema needed to connect to a database.

It has only one section *database-configuration* where the user is supposed to specify the connection type, the database name, the username, password, and extra parameters needed to connect to a database. In this case, most of the options are of type :text.

3.1 Built-in option types

3.1.1 Text

The text option type is specified with :text. It ensures that the option value is of type string.

Example:

```
(:username "Username" :text :documentation "The database engine username") (:password "Password" :text :documentation "The database engine password")
```

3.1.2 Integer

The integer option type is specified with *:integer*. It ensures that the option value is of type integer.

Example:

```
(:port "Port" :integer :documentation "Web application port")
```

3.1.3 Boolean

The boolean option type is specified with *:boolean*. It ensures that the option value is of type boolean (t or nil).

Example:

```
(:catch-errors-p "Catch errors?" :boolean :documentation "Whether to handle application
```

3.1.4 Email

The email option type is specified with *:email*. It ensures that the option value is a valid email string.

Example:

```
(:port "Email" :email :documentation "User email")
```

3.1.5 Url

The url option type is specified with *:url*. It ensures that the option value is a valid url. The option value is converted to a url (cl-url) if it is a string, or left unmodified if already a url.

Example:

```
(:host "Host" :url :documentation "The web application host")
```

3.1.6 Pathname

The pathaname option type is specified with *:path*. It ensures that the option value is a valid pathname and the file or directory exists. The option value is converted to a pathname if it is a string, or left unmodified if already a pathname.

Example:

```
(:stylesheet "Stylesheet" :pathname :documentation "The stylesheet file")
```

3.1.7 One of

The *one of* option type is specified with *:one-of* followed by the list of options, all between parenthesis. It is ensured that the option value is one of the options listed. Options are specified as a list with the option-identifier as a keyword, and the option title with a string.

Example:

3.1.8 List

The *list* option type is specified with *:list* followed by the list of options, all between parenthesis. It is ensured that the option value is a subset of the options listed. Options are specified as a list with the option-identifier as a keyword, and the option title with a string.

Example:

4 Configurations

How to define configurations

4.1 Working with configurations

The API for working with configurations

4.2 Configurations serialization

There are two output backends: an sexp-backend and a xml-backend

5 Installer

CL-Config provides machinery for building your application installers.

In CL-Config an application installer is an instance of the class *installer*. Installers are funcallable, and the idea is to think of installers as a function returning other function, that is, they follow a Continuation Passing Style design.

Some installers features:

- They are funcallable
- They are independent of the UI. You can think of an installer as some kind of Controller in MVC. There's a web frontend available for installers; we plan to build some lighter-weight frontends, such as installing from the REPL or from an neurses interface.
- They follow a continuation passing design.

10085A6701>))

There's a Domain Specific Language for defining installers and in particular, wizard installers. Wizard installers are those that asks for data in different sections or "pages" to complete the installation.

To define installers, there are three macros: define-installer. define-wizard-installer and define-standard-installer.

```
An example of an installer session:
  CFG> *i*
  #<WIZARD-INSTALLER MY-INSTALLER "My installer" 1006C2AB99>
We use funcall to start interacting with the installer:
  CFG> (funcall *i*)
  (:SECTION :WEBAPP-CONFIGURATION "Web configuration")
The web configuration section starts
  CFG> (funcall *i*)
  (:INPUT (HTTP-SERVER HOST PORT))
We are asked to input the :http-server, the :host and the :port
  CFG> (funcall *i* :http-server :apache :host "localhost" :port 8080)
  (:SECTION :DATABASE-CONFIGURATION "Database configuration")
Success. Now we enter the database configuration section.
  CFG> (funcall *i*)
  (:INPUT (NAME HOST USERNAME PASSWORD CONNECTION-TYPE))
We are asked to enter database parameters:
  CFG> (funcall *i* :name "my-database" :host "localhost" :username "mariano" :password
  (:ERRORS
   (#<VALIDATION-ERROR
      FOO value should be one of (SOCKET TCP) on #<ONE-OF-CONFIGURATION-OPTION
                                                       #<CONFIGURATION-SCHEMA-OPTION■
                                                         CONNECTION-TYPE "Connection type"
■
                                                         1005BDF081> F00
```

10085A57F1>

We entered the parameters, but the :connection-type is not valid. We have to try again.

```
CFG> (funcall *i*)
  (:INPUT (NAME HOST USERNAME PASSWORD CONNECTION-TYPE))
  CFG> (funcall *i* :name "my-database" :host "localhost" :username "mariano" :password
  (:SECTION :LOGGING-CONFIGURATION "Logging configuration")

We succeed this time, and we enter the logging configuration section
  CFG> (funcall *i*)
  (:INPUT (BACKEND DEBUGGING-LEVELS OUTPUT-LOCATION ACTIVE-LAYERS))

We are asked for logging section parameters
  CFG> (funcall *i* :backend :log5 :debugging-levels '(:info) :output-location :file :ac
  #<CONFIGURATION MY-CONFIG "My config" 1006D3DB91>
```

We finish the installation and we get the configured configuration as result.

6 Examples

```
(define-configuration-schema database-configuration ()
  (:title "Database configuration")
  (:documentation "Database configuration")
  (:section :database-configuration "Database configuration"
      (:documentation "Section for configuring the database")
      (:connection-type "Connection type"
          (:one-of (:socket "Socket"
    :configuration 'db-socket-configuration)
  (:tcp "TCP"
:configuration 'db-tcp-configuration)))
      (:username "Username" :text :documentation "The database engine username")
      (:password "Password" :text :documentation "The database engine password")
      (:database-name "Database name" :text)
      (:database-parameters "Database parameters" :text :default "" :advanced t)))
(define-configuration-schema cl-config-application-configuration ()
  (:title "CL-CONFIG Application Configuration")
 (:documentation "CL-CONFIG Application Configuration")
 (:section :configuration-settings "Configuration settings"
    (:load-configs-from-file "Load configurations from file"
     :boolean :default t)
    (:load-configs-file "Configurations file" :pathname :optional t)
    (:select-config-from-file "Select configuration from file"
      :boolean :default t)
    (:select-config-file "Select configuration file" :pathname :optional t)))
(define-configuration-schema db-socket-configuration ()
    (:title "Socket configuration")
    (:section :db-socket-configuration "Socket configuration"
        (:path "Socket" :pathname
               :default "/tmp/socket.soc")))
(define-configuration-schema db-tcp-configuration ()
    (:title "TCP configuration")
    (:section "TCP configuration"
        (:url "URL" :url
              :default "localhost")))
(define-configuration-schema logging-configuration ()
    (:title "Logging configuration")
    (:documentation "Logging configuration")
    (:section :logging-configuration "Logging configuration"
        (:documentation "Logging configuration")
        (:backend "Backend"
```

```
(:one-of (:log5 "Log5")))
(:debugging-levels "Debugging levels" (:list (:info "Info")
    (:warning "Warning")
     (:profile "Profile")))
(:output-location "Output location"
                    (:one-of (:standard-output "Standard output"
       :default *standard-output*)
    (:file "File" :default "/tmp/log.log"))
    :default '*standard-output)
       (:active-layers "Active layers"
(:list
(:debugging "Debugging"
    :configuration 'debugging-layer)
(:database "Database"
    :configuration database-layer)
(:control-flow "Control flow")
(:system "System")))))
(define-configuration-schema webapp-configuration (logging-configuration)■
    (:title "Web application configuration")
    (:documentation "Web application configuration")
    (:section :webapp-configuration "Web application configuration"
        (:documentation "Web application configuration")
        (:http-server "HTTP server"
            (:one-of (:apache "Apache"
      :configuration 'apache-configuration)
                    (:hunchentoot "Hunchentoot"
 :configuration 'hunchentoot-configuration)))
        (:host "Host" :text :default "localhost")
(:port "Port" :integer :default 8080)
(:catch-errors "Catch errors" :boolean :default t)))
(define-configuration-schema standard-configuration
    (cl-config-application-configuration
    webapp-configuration
    database-configuration)
      (:title "Standard configuration")
      (:documentation "Standard configuration for a Gestalt application")
     (:page-title "Page title" :text :default "Gestalt application"))
(define-configuration standard-configuration ()
  (:title "Standard configuration")
  (:configuration-schema standard-configuration)
 (:section :database-configuration
   (:connection-type :socket
      :value2
     '(:db-socket-configuration
```

```
(:path "/tmp/my-socket.soc")))
    (:username "root")
   (:password "root")
   (:database-name "standard-database"))
 (:section :webapp-configuration
    (:http-server :hunchentoot))
  (:section :logging-configuration
    (:active-layers (:debugging))
    (:output-location :standard-output)
    (:debugging-levels (:info))
    (:backend :log5)))
(define-configuration debug-configuration (standard-configuration)
    (:configuration-schema standard-configuration)
    (:title "Debug configuration")
    (:section :database-configuration
        (:database-name "debug-database"))
    (:section :logging-configuration
      (:output-location :standard-output)
      (:active-layers (:debugging :database))
      (:debugging-levels (:info :warning :error)))
    (:section :webapp-configuration
      (:catch-errors nil))
    (:documentation "Debugging configuration scheme"))
(define-configuration test-configuration (standard-configuration)
    (:configuration-schema standard-configuration)
    (:title "Test configuration")
    (:section :database-configuration
        (:database-name "test-database"))
    (:section :logging-configuration
      (:output-location :file :value2 "/tmp/test.log")
      (:active-layers (:debugging :database) :inherit t)
       (:debugging-levels (:warning :error)))
    (:documentation "Testing configuration scheme"))
```

The typical attributes types are, :text, where the user fill text in; :one-of options*, where the user chooses one of the options in options*; :list list*, where the user selects one or more of the items of the list *list; :bool, a boolean, :maybe option, where the user can disable or enable option, etc.

Configurations can inherit from several configurations (that act like mixins). The same as with classes or models or templates. So, for example, web-app-configuration inherits from logging-configuration. That means the web-app-configuration will have the sections defined in logging-configuration too.

Documentation is used as a section or configuration help from the UI. From the UI, each section is shown collapsable and there's and option for showing/hiding advanced fields, and the help button.

The user can define several configuration schemes for an application and switch between the configurations. For example, there will probably be a "development configuration", a "deployment configuration", a "testing configuration", and so on.

There's no need for a GUI, although it is desirable. We can define configurations with files, for example:

```
(define-configuration-scheme standard-configuration-scheme ()
     (:configuration standard-configuration)
     (:database-configuration
          (:connection-type :socket
              (:db-socket-configuration
                 (:path "/tmp/my-socket.soc")))
         (:username "root")
          (:password "root")
          (:database-name "standard-database"))
     (:webapp-configuration
          (:host "localhost")
          (:http-server :hunchentoot)))
  (define-configuration-scheme debug-configuration-scheme (standard-configuration-scheme
      (:configuration standard-configuration)
      (:database-configuration
          (:database-name "debug-database"))
      (:logging-configuration
          (:output-location :file "/tmp/debug.log")
          (:active-layers :debugging :database
              (:debugging-levels :info :warning :error)))
      (:documentation "Debugging configuration scheme"))
  (define-configuration-scheme test-configuration-scheme (standard-configuration-scheme)
      (:configuration standard-configuration)
      (:database-configuration
           (:database-name "test-database"))
      (:logging-configuration
         (:output-location :file "/tmp/test.log")
          (:active-layers :debugging :database
              (:debugging-levels :warning :error)))
      (:documentation "Testing configuration scheme"))
And then we attach the desired configuration to the application:
  (defapplication my-application (standard-application)
     (:configuration 'debug-configuration-scheme))
```

6.1 Use cases

6.1.1 Debugging

- 6.1.2 Logging
- 6.1.3 Testing
- 6.1.4 Deployment

7 Configuration editing

Configurations can be edited from a web interface.

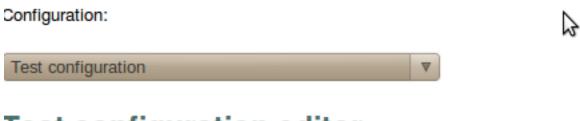

To start the web configuration editor, evaluate:

(require :cl-config-web)

(cfg.web:start-cl-config-web)

and then point your browser to http://localhost:4242

Configurations editor

8 Custom option types

How to define custom option types

9 System reference

cl-config:configuration-installer [Class] Class precedence list: configuration-installer, installer, funcallable-standard-object, function, standard-object, t The class for configuration installers cl-config:configuration-schema [Class] Class precedence list: configuration-schema, standard-object, t Slots: • name — initargs: :name The configuration-schema name • parents — initargs: :parents Configuration-Schema mixins • title — initargs: :title Configuration-Schema title • direct-sections — initargs: :direct-sections Configuration-Schema direct-sections • documentation — initargs: :documentation Configuration-Schema documentation A configuration-schema cl-config:configuration [Class] Class precedence list: configuration, standard-object, t Slots: • name — initargs: :name The configuration name • title — initargs: :title Configuration title The configuration class cl-config:installer [Class] Class precedence list: installer, funcallable-standard-object, function, standard-object, t The main installer class. Installer instances are funcallable cl-config:standard-installer [Class] Class precedence standard-installer, wizard-installer, configuration-installer, installer, funcallable-standard-object, function, standard-object, t standard-intallers are installers used for installing configurations in a wizard fashion

cl-config:wizard-installer

[Class]

Class precedence list: wizard-installer, installer, funcallable-standard-object, function, standard-object, t

The class for wizard installers

cl-config:cfg* path &optional configuration

[Function]

Function for getting a configuration value (the functional version of the cfg macro) path can be one of:

- A list with the form (<section> <option>). Example: (cfg* '(:database-configuration :username))
- A symbol with the form <section>.<option> Example: (cfg*:database-configuration.username)

The default configuration used is *configuration* (the current configuration)

cl-config:find-configuration-schema name

[Function]

Get a configuration-schema by its name

cl-config:find-configuration name

[Function]

Get a configuration by its name

cl-config.web:start-cl-config-web &optional configuration

[Function]

Starts the web configuration editor

Default arguments are in standard-cl-config-web-configuration

Evaluate (cfg.web:start-cl-config-web) and point your browser to http://localhost:4242

cl-config.web:stop-cl-config-web

[Function]

Stops the web configuration editor

cl-config:cfg path &optional configuration

[Macro]

Macro for getting a configuration value. path can be one of:

- A list with the form (<section> <option>). Example: (cfg (:database-configuration :username))
- A symbol with the form <section>.<option> Example: (cfg :database-configuration.username)

The default configuration used is *configuration* (the current configuration)

cl-config:define-configurable-function name args &body body

Macr

Defines a configurable function. See macroexpansion to understand what it does

Example:

(connect database-name username password host)))

And then:

```
(connect :database-name "My database"
                      :host "localhost"
                       :username "foo"
                       :password "bar")
cl-config:define-configuration-schema-option-type type args
                                                                        [Macro]
         &body body
     Define a custom configuration-schema option type. Example:
               (define-configuration-schema-option-type :email (&rest args)
                    (apply #'make-instance 'email-configuration-schema-option-type
               args))
cl-config:define-configuration-schema name parents & rest args
                                                                        [Macro]
     Syntax for defining a configuration-schema.
     Parameters:
      • name - The name of the schema
```

- - parents A list of schema parents
- Comments:
 - A configuration schema can inherit from several parents.
 - A title parameter is required to define the schema (see example below)

Example:

```
(cfg::define-configuration-schema postgres-database-configuration ()
             (:title "Postgres database configuration")
             (:documentation "Postgres database configuration")
             (:section :database-configuration "Database configuration"
                (:documentation "Section for configuring the database")
                (:connection-type "Connection type"
                    (:one-of (:socket "Socket"
              :configuration 'db-socket-configuration)
             (:tcp "TCP"
           :configuration 'db-tcp-configuration)))
                (:username "Username" :text :documentation "The database engine username")
                (:password "Password" :text :documentation "The database engine password")
                (:database-name "Database name" :text)
                (:host "Host" :text :documentation "The database host")
                (:database-parameters "Database parameters" :text :default "" :advanced t))
cl-config:define-configuration-validator configuration-schema
                                                                      [Macro]
        configuration &body body
```

Defines a validator on a configuration. Example:

```
(handler-bind
                (postmodern:connect database-name username password host)
                   (postmodern:database-error (error)
             (cfg::validation-error
              (cl-postgres::message error)))))))
cl-config:define-configuration name parents & rest args
                                                                          [Macro]
     Create and register a configuration Example:
              (\texttt{define-configuration} \ \ \texttt{debug-configuration} \ \ (\texttt{standard-configuration}) \blacksquare
               (:configuration-schema standard-configuration)
               (:title "Debug configuration")
               (:section :database-configuration
                   (:database-name "debug-database"))
               (:section :logging-configuration
                  (:output-location :standard-output)
                  (:active-layers (:debugging :database))
                  (:debugging-levels (:info :warning :error)))
               (:section :webapp-configuration
                 (:catch-errors nil))
               (:documentation "Debugging configuration scheme"))
cl-config:define-installer name &key &body body
                                                                          [Macro]
     Define a vanilla installer
cl-config:define-option-processor type value &body body
                                                                          [Macro]
     Define a processor for a custom type
cl-config:define-option-validator type value condition error-msg
                                                                          [Macro]
         &rest args
     Define a validator for a custom type
     Example:
                (define-option-validator email-configuration-schema-option-type
                   (value option)
                     (valid-mail-address-p value)
                           "~A is not a valid email address in ~A" value option)
cl-config:define-standard-installer name &key &body body
                                                                          [Macro]
     Defines a standard-installer
cl-config:define-wizard-installer name &key &body body
                                                                          [Macro]
     Define a wizard installer
cl-config:idefun name args &body body
                                                                          [Macro]
     Defines a installer function
cl-config:make-configuration name parents & rest args
                                                                          [Macro]
     Create a configuration without registering it globally
```

cl-config:*configuration*

[Variable]

cl-config:with-configuration-section section-name &body body [Macro] Executes body in the context of the given configuration section Example: (with-configuration test-configuration (with-configuration-section :database-configuration (cfg :username))) cl-config:with-configuration-values values configuration &body [Macro] body Macro for binding a configuration option values Example: (with-configuration test-configuration (with-configuration-section :database-configuration (with-configuration-values (username) *configuration* username))) cl-config:with-configuration configuration-name &body body [Macro] Executes body in the context of the given configuration Example: (with-configuration test-configuration (cfg (:database-configuration :username))) cl-config:with-current-configuration-values values &body body [Macro] The same as with-configuration-values but using the current configuration *configuration* Example: (with-configuration test-configuration (with-configuration-section :database-configuration (with-current-configuration-values (username) username))) cl-config:with-input bindings &body body [Macro] Wizard installer operation. Asks for input. cl-config:with-schema-validation &optional &body body [Macro] Executes body validating or or not the configurations created in body context (depending the value of value). The default when using this macro is to not validate. This macro is more commonly used for internal implementation options. Example: (with-schema-validation (nil) (setf (cfg :database-configuration.username) 2323)) cl-config:*configuration-schemas* [Variable] The defined configuration-schemas. Access the configuration-schemas through the findconfiguration-schema function

The current configuration. Use with-configuration macro to set this

[Variable]

cl-config:*configurations* [Variable]
The defined configurations. Use find-configuration to access configurations by name
